

STEP

LOGO DEVELOPMENT

Should embody company values like innovation, trust, futuristic, and state-of-the-art technology.

Mascots

- Could be an eagle, octopus, d

AI labeling companies typically use several programming languages, depending on the part of the workflow they're focusing on. Here are the most common ones:

1. **Python**

- The most popular language in AI and machine learning.
- Used for data processing, building annotation tools, and integrating with machine learning models.
- Libraries like Pandas, NumPy, and TensorFlow help with data handling and AI tasks.

2. **JavaScript (and TypeScript)**

- Used for building web-based labeling tools and annotation interfaces.
- Frameworks like React or Angular make it easier to create interactive labeling platforms.

3. **Java**

- Sometimes used for backend services, especially in enterprise-grade annotation systems.

4. **C++**

- Less common but used in performance-critical parts, like real-time image or video processing.

5. **SQL**

- For managing databases where labeled data is stored.

6. **Other scripting languages** like Ruby or PHP can be used, but Python and JavaScript dominate.

Python and JavaScript are the main ones. For the actual labeling (manual work), human annotators usually use tools built with these languages under the hood.

1-Year AI Product & Pitch Plan for Two Teens

Months 1-2: Research & Ideation

- **Learn basics of AI and coding:** Focus on Python, machine learning concepts, and AI platforms (e.g., OpenAI, TensorFlow, Hugging Face).
- **Brainstorm problems:** List problems you care about—ideally, where AI can add real value.
- **Market research:** Check if others are solving these problems, and identify gaps or improvements.
- **Choose one clear problem** to solve with your AI product.

Goal: Pick a focused AI product idea with potential users.

Months 3-5: MVP Development

- **Collect or find datasets:** Use open datasets or create your own labeled data if needed.
- **Build your MVP:** Use pre-trained models and APIs for faster progress (e.g., use GPT for text tasks or Google Vision for image recognition).
- **Develop a simple user interface:** Could be a web app or mobile app—just enough to demo your idea.

Goal: Have a working MVP that solves the core problem.

Months 6-7: User Testing & Iteration

- **Find early users/testers:** Friends, family, online communities—get real feedback.
- **Improve your product:** Fix bugs, improve AI accuracy, and simplify user experience.
- **Measure impact:** Collect basic metrics to show your product's usefulness.

Goal: Validate your product works and users like it.

Months 8-9: Business Model & Pitch Prep

- **Define your business model:** How will you make money? Subscription, licensing, freemium?
- **Create your pitch deck:** Include
 - Problem & opportunity
 - Your AI solution
 - Market size & competition
 - Team (that's you two!)
 - Progress & MVP demo
 - Roadmap & funding needs
- **Practice your pitch:** Clear, confident, and under 10 minutes.

Goal: Ready to impress investors with your story and product.

Months 10-12: Networking & Pitching

- **Find opportunities:** Local startup competitions, school programs, AI incubators, online pitch events.

- **Connect with mentors:** They can give advice, help refine your pitch, and introduce you to investors.
- **Pitch to investors:** Share your demo, explain why your product matters, and show your vision.
- **Gather feedback:** Use investor and mentor input to improve.

Goal: Get your first meetings with investors or startup programs.

Extra Tips

- **Document everything:** Keep records of your code, data, feedback, and improvements.
- **Stay flexible:** Be ready to pivot if user feedback or market data suggest changes.
- **Balance learning and building:** Spend time both gaining skills and actually building your product.
